Psych 215L: Language Acquisition

Lecture 3
Speech Perception

Sounds of Language (Speech Perception)

Learner’s job: Identify phonemes (contrastive sounds that signal a change in meaning)

Phonemes are language-specific - r-l is a phonemic contrast in English but not in Japanese

Kids of the world require knowledge of phonemes before they can figure out what different words are - and when different meanings are signaled by different words

About Speech Perception

Important: Not all languages use the same contrastive sounds.
Languages draw from a common set of sounds (which can be represented by the International Phonetic Alphabet (IPA)), but only use a subset of that common set.

Child’s task: Figure out what sounds their native language uses contrastively.

meaningful sounds in the language: “contrastive sounds” or phonemic contrasts

big vs. pig

Lisa = Risa for some of my Japanese friends
Speech Perception: Computational Problem

Divide sounds into contrastive categories (phonemes)
Here, 23 acoustically-different sounds are clustered into 4 contrastive categories. Sounds within categories are perceived as being identical to each other.

Real world data are actually much harder than this...
(from Swingley 2009)

Categorical Perception

Categorical perception occurs when a range of stimuli that differ continuously are perceived as belonging to only a few categories with no degrees of difference within a given category.

Acoustic-Level Information

Includes: timing and frequency
Tones: frequency (close-up)
Vowels combine acoustic energy at a number of different frequencies.

Different vowels ([a] "ah", [i] "ee", [u] "oo" etc.) contain acoustic energy at different frequencies.

Listeners must perform a frequency analysis of vowels in order to identify them (Fourier Analysis).

Acoustic-Level Information

Language sounds

Male Vowels (close up)

Acoustic-Level Information

Language sounds

Female Vowels (close up)

Synthesized Speech

Allows for precise control of sounds.

Valuable tool for investigating perception.
Acoustic-Level Information

Language sounds
Timing: Voicing

Acoustic-Level Information

Language sounds
Timing: Voice Onset Time (VOT)

60 ms

English VOT production
Not uniform - there are 2 categories (distribution is bimodal)

Perception of stimuli: 2 categories
Perceiving VOT

‘Categorical Perception’: \( dQ \) vs. \( tQ \)

Decision between \( d/t \)

Identification task: “Is this sound \( dQ \) or \( tQ \)?”

Time to make decision

Longer decision time at category boundary

More uncertainty/error at category boundary

Discrimination Task

“Are these two sounds the same or different?”

<table>
<thead>
<tr>
<th>Same/Different</th>
<th>0ms</th>
<th>60ms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Same/Different</td>
<td>0ms</td>
<td>10ms</td>
</tr>
<tr>
<td>Same/Different</td>
<td>40ms</td>
<td>40ms</td>
</tr>
</tbody>
</table>

Why is this pair difficult?

(i) Acoustically similar?

(ii) Same Category?

Across-Category Discrimination is Easy

Within-Category Discrimination is Hard
Cross-language Differences

Identification task:
English speakers can discriminate r and l, and seem to show a similar pattern of categorical perception to what we saw for d vs. t

Miyawaki et al. 1975

Cross-language Differences

Discrimination task:
English speakers have higher performance at the r/l category boundary, where one sound is perceived as r and one sound is perceived as l. Japanese speakers generally perform poorly (at chance), no matter what sounds are compared because r and l are not contrastive for them.

Miyawaki et al. 1975

Cross-language Differences

Hindi
dental [d]
(tip of tongue touches back of teeth)

retroflex [D]
(tongue curled so tip is behind alveolar ridge)

English [d] is usually somewhere between these
Cross-Language Differences

Salish (Native North American language):
- Glottalized voiceless stops

- Uvular – tongue is raised against the velum

- Velar – tongue is raised behind the velum

(they are actually ejectives - ejective is produced by obstructing the airflow by raising the back of the tongue against or behind the velum)

Infant Speech Perception

How do we tell what infants know, or use, or are sensitive to?

Researchers use indirect measurement techniques.

Some information from the High Amplitude Sucking (HAS) paradigm (Eimas et al. 1971)

Infants have sophisticated discrimination abilities, but they don't abstract sounds into categories the way that adults do.

Infant perception
- "d1"  
- "t1"  

Phonemic category

Adult perception
- "d2"  
- "t2"  

Phonemic category
Kids...  

This ability to distinguish sound contrasts extends to phonemic contrasts that are non-native. (Japanese infants can discriminate contrasts used in English but not in Japanese, like r/l.) This goes for both vowels and consonants.

...vs. adults

Adults can't, especially without training - even if the difference is quite acoustically salient.

So when is this ability lost?

And what changes from childhood to adulthood?

Speech Perception of Non-Native Sounds

Comparing perceptual ability

Werker et al. 1981: English-learning 6-8 month olds compared against English & Hindi adults on English & Hindi contrasts

But when after 6-8 months is the ability to lost? Werker & Tees (1984)

Key into “critical period” hypothesis for language (Lenneberg 1967) - when language can be learned natively

“To test for this critical period, children of 12 and 8 years were tested, with the expectation that the 8-year-olds but not the 12-year-olds would be able to discriminate nonnative contrasts. English-speaking children of both ages, however, performed like English-speaking adults...study was extended to 4-year old children, who actually performed most poorly of all on nonnative contrasts...findings revealed that experience must begin to influence speech perception long before 4, certainly well before the critical period suggested by Lenneberg.”

Speech Perception of Non-Native Sounds

But when after 6-8 months is the ability to lost? Werker & Tees (1984)

Salish & Hindi contrasts

Change happens somewhere around 8-10 months, depending on the sound contrast.

See Yoshida et al. (2015) for evidence that infants have some malleability still at 10 months, but it’s much less than at 6 or 8 months.
Discovering contrastive sounds: What's the point of it again?

The idea is that once children discover the meaningful sounds in their language, they can begin to figure out what the words are.

Ex: An English child will know that "cat" and "caat" are the same word (and should have the same meaning).

As adults, we can look at a language and figure out what the contrastive sounds are by looking at what changes a word's meaning. But children can't do this - they figure out the contrastive sounds before they figure out words and word meanings.

More about contrastive sounds

There are a number of acoustically salient features for sounds. All it takes for sounds to be contrastive is for them to have "opposite" values for one feature.

Example:

English sounds "k" and "g" differ only with respect to voicing. They are pretty much identical on all other features. Many contrastive sounds in English use the voicing feature as the relevant feature of contrast (p/b, t/d, s/z, etc.). However, there are other features that are used as well (air flow, manner of articulation, etc.).

Task for the child: Figure out which features are used contrastively by the language. Contrastive sounds for the language will usually vary with respect to one of those features.

Experimental Study:
Dietrich, Swingley & Werker (2007)

Testing children's perception of contrastive sounds

Dutch and English contrastive features differ.

In English, the length of the vowel is not contrastive

"cat" = "caat"

In Dutch, the length of the vowel is contrastive

"cat" ≠ "caat"

(Japanese also uses this feature)

Does the data distribution show this?

Dutch and English vowel sounds in the native language environment also seem to differ

"...studies suggest that differences between the long and short vowels of Dutch are larger than any analogous differences for English."
Does the data distribution show this?

Dutch and English vowel sounds in the native language environment also seem to differ.

</tr>
</tbody>
</table>
Learning from real data distributions

How do we know that children are sensitive to distributional information?

Maye, Werker, & Gerken (2002)

Created synthetic sounds ranging from [da] to [ta] that were non-native for the infants (because they were unaspirated).

Maye, Werker, & Gerken (2002)

- Familiarized 6 to 8-month-old infants to one of two sets
  - Bimodal Set: Sounds on the ends near [da] and [ta].
  - Unimodal Set: Sounds in the middle.
- Test preference for:
  - 3 6 3 6… (Alternating) vs. 3 3 3 3… (Non-alternating) stimuli

Maye, Werker, & Gerken (2002)

<table>
<thead>
<tr>
<th></th>
<th>Alternating trials (s)</th>
<th>Non-Alternating trials (s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>6 months Unimodal</td>
<td>4.85 (0.47)</td>
<td>4.53 (0.51)</td>
</tr>
<tr>
<td>8 months Unimodal</td>
<td>4.98 (0.63)</td>
<td>5.23 (0.56)</td>
</tr>
<tr>
<td>6 months Bimodal</td>
<td>5.66 (0.44)</td>
<td>6.41 (0.32)</td>
</tr>
<tr>
<td>8 months Bimodal</td>
<td>5.45 (0.52)</td>
<td>6.15 (0.56)</td>
</tr>
</tbody>
</table>
Infants trained on the Bimodal data had a novelty preference for non-alternating trials. They learned to expect alteration, and were surprised by non-alteration.

Maye, Werker, & Gerken (2002)

Infants trained on the Unimodal data did not prefer/disprefer one over the other. They did not seem to learn any expectation.

Maye, Werker, & Gerken (2002)

Dutch and English vowel sounds in the native language environment also seem to differ...

"...studies suggest that differences between the long and short vowels of Dutch are larger than any analogous differences for English."

Back to Dietrich, Swingley, & Werker (2007)

Dutch children interpret vowel duration as a meaningful contrast because the distribution is more bimodal

Implication: Change to vowel duration = new word

English children should not interpret vowel duration as a meaningful contrast because the distribution is more unimodal

Implication: Change to vowel duration = same word as before

Back to Dietrich, Swingley, & Werker (2007)
Dietrich, Swingley, & Werker (2007)

Tests with 18-month-old children who know some words (and so have figured out the meaningful sounds in their language)

“Switch” Procedure: measures looking time

...this is a tam...look at the tam

Habituation

Same:
look at the tam!
Switch:
look at the taam!

Test

</table>

Test

(This is a control condition to make sure English kids can do the task when the sound is contrastive for them)
Dietrich, Swingley, & Werker (2007)

Just a note that experimental data with infants is messier than it sounds.

Implications of experiments 1, 2, and 3: Dutch children recognize vowel duration as contrastive for their language while English children do not. This can only be due to the data encountered by each set of children in their language.

Dutch children have a category boundary approximately here. English children do not.

What drives children to learn the distinction?

“One frequently raised hypothesis... is that it is driven by contrast in the vocabulary. Dutch children might learn that [a] and [e:] are different because the words [stat]... and [sta:]... mean different things... however, children that young do not seem to know many word pairs that could clearly indicate a distinction between [a] and [e:].”

“The other current hypothesis is that children begin to induce phonological categories "bottom-up", based on their discovery of clusters of speech sounds in phonetic space... undoubtedly implicated in infants’ early phonetic category learning, which begins before infants know enough words for vocabulary-based hypotheses to be feasible..."
Dietrich, Swingley, & Werker (2007)

“A necessary condition for such learning to be the driving force behind Dutch children’s phonological interpretation in the present studies is that long and short vowels be more clearly separable in Dutch than in English… preliminary examination of this problem using corpora of Dutch child-directed speech indicated that the set of long and short instances formed largely overlapping distributions.”

Implication: Dutch children need other cues to help them out

Swingley (2009)

One potential source of information: keep some contextual information for each vowel sound (what word it came from, if it comes from a frequent word).
